Received: December 19, 1994; In Final Form: June 23, 1995<sup>®</sup>

The UV absorption spectra of CF<sub>3</sub>CClH and CF<sub>3</sub>CClHO<sub>2</sub> radicals have been investigated. The CF<sub>3</sub>CClH spectrum was quantified over the wavelength range 225–280 nm. The absorption cross section at 250 nm was  $(139 \pm 16) \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$ . The absorption spectrum for CF<sub>3</sub>CClHO<sub>2</sub> was quantified over the wavelength range 225–290 nm, and at 250 nm  $\sigma_{250 \text{ nm}} = (258 \pm 30) \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$ . The kinetics of the reactions of the peroxy radical CF<sub>3</sub>CClHO<sub>2</sub> with NO and NO<sub>2</sub> were studied and the derived rate constants were  $k_3 = (1.0 \pm 0.3) \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$  and  $k_4 = (6.4 \pm 1.5) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ , respectively. The self-reaction rate for the CF<sub>3</sub>CClHO<sub>2</sub> radicals was measured and a value of  $k_{6\text{obs}} = (4.4 \pm 0.3) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$  was obtained. The reactions of F atoms with CF<sub>3</sub>CH<sub>2</sub>Cl and of CF<sub>3</sub>CClH with O<sub>2</sub> were found to proceed with rate constants of  $k_8 = (2.0 \pm 0.6) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$  and  $k_2 = (1.4 \pm 0.1) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ , respectively. The reaction of CF<sub>3</sub>CClHO<sub>2</sub> radicals with NO gives NO<sub>2</sub>, and by implication CF<sub>3</sub>CClHO radicals, which in the atmosphere (a) react with O<sub>2</sub> to give CF<sub>3</sub>C(O)Cl and (b) decompose to give, most likely, CF<sub>3</sub> radicals and HC(O)Cl. In 700 Torr of N<sub>2</sub> diluent the rate constant ratio  $k_{\text{O}_2}/k_{\text{diss}} = (2.1 \pm 0.4) \times 10^{-19} \text{ cm}^3 \text{ molecule}^{-1}$ . As part of the present work, relative rate techniques were used to measure rate constants for the reactions of Cl and F atoms with CF<sub>3</sub>CH<sub>2</sub>Cl of  $(6.8 \pm 1.2) \times 10^{-15}$  and  $(2.1 \pm 0.5) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ , respectively. All experiments were performed at  $296 \pm 2 \text{ K}$ .

## 1. Introduction

As agreed in the latest amendment to the Montreal Protocol, the production of CFCs is to be phased out by the end of 1995. Hydrofluorocarbons (HFCs) and hydrochlorofluorocarbons (HCFCs) are important CFC replacements. To place discussions of the environmental impact of HFCs and HCFCs on a sound technical basis requires a detailed knowledge of their atmospheric chemistry. As part of a collaboration between our laboratories to survey the atmospheric chemistry of important HFCs and HCFCs, we have investigated HCFC-133a, CF<sub>3</sub>CH<sub>2</sub>Cl. This compound is not of present commercial importance, although it is structurally similar to HFC-134a (CF<sub>3</sub>CH<sub>2</sub>F) which is of a major economic importance. Information on the chemistry of HCFC-133a may provide an interesting comparison with the atmospheric chemistry of HFC-134a.

In contrast to CFCs, HCFCs and HFCs have C–H bonds and are susceptible to attack by OH radicals in the lower atmosphere. Reactions that are expected to be important in the atmospheric chemistry of HCFC-133a are as follows:<sup>1</sup>

In the present work, we have studied the kinetics of reactions 2–4 and 6 using a pulse radiolysis technique. In addition, the fate of the alkoxy radical CF<sub>3</sub>CClHO was determined using a FTIR–smog chamber system. Results are reported herein.

## 2. Experimental Section

Two different experimental systems were used in the present work. Both experimental systems have been described in detail in previous publications<sup>2,3</sup> and will only be discussed briefly here.

**2.1. Pulse Radiolysis System.** CF<sub>3</sub>CH<sub>2</sub>Cl/O<sub>2</sub>/SF<sub>6</sub> mixtures were radiolyzed in a 1 L stainless steel reaction cell using a 30 ns pulse of 2 MeV electrons from a Febetron 705B field emission accelerator. SF<sub>6</sub> was always in great excess and was used to generate fluorine atoms:

UV absorptions attributed to transient radical species were followed by multipassing the output of a pulsed 150 W xenon arc lamp through the reaction cell using internal White cell optics. Total path lengths of 80 and 120 cm were used. After

<sup>®</sup> Abstract published in *Advance ACS Abstracts*, August 15, 1995.

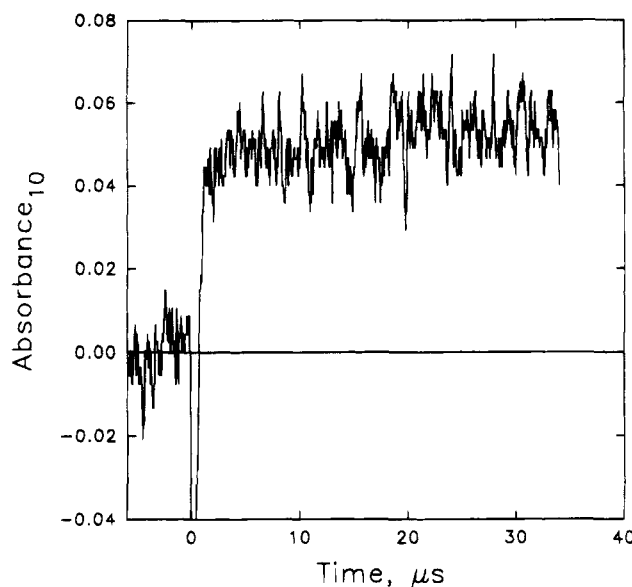

passing through the cell the light was guided through a 1 m McPherson grating UV-vis monochromator and detected with a Hamamatsu photomultiplier. The spectral resolution was 0.8 nm. Reagent concentrations used were SF<sub>6</sub>, 900–950 mbar; O<sub>2</sub>, 0–40 mbar; CF<sub>3</sub>CH<sub>2</sub>Cl, 0–50 mbar; NO, 0.23–0.88 mbar; and NO<sub>2</sub>, 0.24–0.81 mbar. All experiments were performed at 296 K. Ultra high purity O<sub>2</sub> was supplied by L'Air Liquide, SF<sub>6</sub> (99.9%) was supplied by Gerling and Holz, NO (99.8%) from Messer Griesheim, and CF<sub>3</sub>CH<sub>2</sub>Cl (>97%) was obtained from Fluorochem. All reagents were used as received. FTIR spectroscopy was used to search for impurities in the CF<sub>3</sub>CH<sub>2</sub>Cl sample; none were found. The partial pressures of the different gases were measured using a Baratron membrane manometer with a resolution down to 10<sup>-5</sup> bar.

Seven sets of experiments were performed using the pulse radiolysis system. First, the spectrum of CF<sub>3</sub>CClH was recorded by observing the maximum transient absorption following pulse radiolysis of mixtures of 30 mbar CF<sub>3</sub>CH<sub>2</sub>Cl and 970 mbar of SF<sub>6</sub>. Second, the rate constant for the reaction of F atoms with CF<sub>3</sub>CH<sub>2</sub>Cl was determined by monitoring the maximum transient absorption following the radiolysis of CF<sub>3</sub>CH<sub>2</sub>Cl/O<sub>2</sub>/SF<sub>6</sub> mixtures as a function of the [CF<sub>3</sub>CH<sub>2</sub>Cl]/[O<sub>2</sub>] ratio. Third, the UV spectrum of CF<sub>3</sub>CClHO<sub>2</sub> was recorded by observing the maximum transient absorption following the radiolysis of CF<sub>3</sub>CH<sub>2</sub>Cl/O<sub>2</sub>/SF<sub>6</sub> mixtures. Fourth, the rate constant for the reaction between CF<sub>3</sub>CClH with O<sub>2</sub> was measured by varying the O<sub>2</sub> concentration and studying the rate of formation of the CF<sub>3</sub>CClHO<sub>2</sub> radical at short times (20 μs). Fifth, the rate constant for the self-reaction of CF<sub>3</sub>CClHO<sub>2</sub> radicals was determined by studying the dependence of the rate of decay of the transient absorption on the initial radical concentration using CF<sub>3</sub>CH<sub>2</sub>Cl/O<sub>2</sub>/SF<sub>6</sub> mixtures. Sixth, the rate of reaction 3 was determined by adding NO to the mixture and monitoring the rate of formation of NO<sub>2</sub> at 400 nm. Seventh, the rate of reaction of CF<sub>3</sub>CClHO<sub>2</sub> radicals with NO<sub>2</sub> was determined using the radiolysis of CF<sub>3</sub>CH<sub>2</sub>Cl/O<sub>2</sub>/SF<sub>6</sub>/NO<sub>2</sub> mixtures with the NO<sub>2</sub> loss rate monitored at 400 nm.

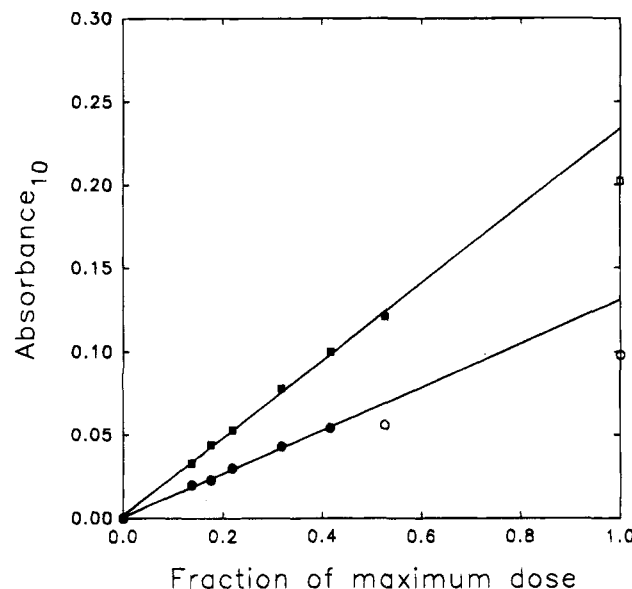

**2.2. FTIR-Smog Chamber System.** The FTIR system was interfaced to a 140 L Pyrex reactor. Radicals were generated by the UV irradiation of mixtures of 69–1100 mTorr of CF<sub>3</sub>CH<sub>2</sub>Cl, 0.2–0.4 Torr of Cl<sub>2</sub> or 0.2–0.5 Torr of F<sub>2</sub>, and 2.3–700 Torr of O<sub>2</sub> in 700 Torr total pressure with N<sub>2</sub> diluent at 296 K using 22 blacklamps (760 Torr = 1013 mbar). The loss of reactants and the formation of products were monitored by FTIR spectroscopy, using an analyzing path length of 27 m and a resolution of 0.25 cm<sup>-1</sup>. Infrared spectra were derived from 32 co-added spectra. CF<sub>3</sub>CH<sub>2</sub>Cl, CF<sub>3</sub>C(O)Cl, CF<sub>3</sub>CHO, and HC(O)Cl were monitored using their characteristic features over the wavenumber ranges 770–870, 720–900 and 1750–1850, 700–750 and 1750–1850, and 710–760 cm<sup>-1</sup>, respectively. Reference spectra were acquired by expanding known volumes of reference materials into the reactor.

### 3. Results

**3.1. Pulse Radiolysis System.** *UV Absorption Spectrum of CF<sub>3</sub>CClH Radicals.* The UV absorption spectrum was studied by observing the maximum transient absorption at short times (40 μs) following the radiolysis of mixtures of 30 mbar of CF<sub>3</sub>CH<sub>2</sub>Cl and 970 mbar SF<sub>6</sub>. The spectrum was quantified in the wavelength range 225–275 nm. The UV path length was 80 cm. An example of an absorption transient is given in Figure 1. A series of experiments at 250 nm using different radiolysis doses was performed to determine conditions where F atoms are converted stoichiometrically into CF<sub>3</sub>CClH radicals. In Figure 2, the maximum absorption is plotted as a function of radiolysis dose. The datapoint at zero radiolysis dose was

**Figure 1.** Absorption transient for mixtures of 30 mbar of CF<sub>3</sub>CH<sub>2</sub>Cl and 970 mbar of SF<sub>6</sub> at 230 nm. The radiolysis dose used was 42% of full dose.

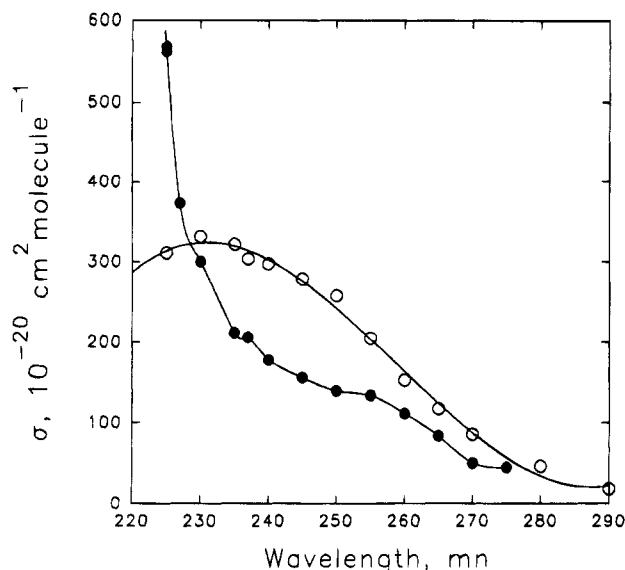

**Figure 2.** Maximum transient absorption (circles) as a function of radiolysis dose at 250 nm for mixtures of 30 mbar of CF<sub>3</sub>CH<sub>2</sub>Cl and 970 mbar of SF<sub>6</sub>. The straight line is a linear least-squares fit through the low dose data. Maximum transient absorption (squares) vs radiolysis dose at 250 nm and 40 mbar of CF<sub>3</sub>CH<sub>2</sub>Cl, 20 mbar of O<sub>2</sub>, and 940 mbar of SF<sub>6</sub>.

obtained by filling the reaction cell with reactants, placing a stainless steel plate in between the electron source and cell and then firing the source. No transient absorption signal was observed, and hence the point at the origin in Figure 2. It can be seen that for doses less than 40% of full dose the maximum absorption is proportional to the radiolysis dose, and hence the initial F atom concentration. At higher doses the measured absorption is smaller than expected from a linear extrapolation of the low dose data. We ascribe this nonlinearity at high doses to unwanted radical-radical reactions such as

Using three pieces of information, (i) the F atom yield at full dose and 1000 mbar of SF<sub>6</sub>,  $(2.8 \pm 0.3) \times 10^{15} \text{ cm}^{-3}$ ,<sup>4</sup> (ii) the slope  $(0.130 \pm 0.004)$  of the linear least-squares fit through

the low dose data in Figure 2, and (iii) the UV path length of 80 cm, we can calculate the absorption cross section of  $\text{CF}_3\text{CClH}$  at 250 nm to be  $(139 \pm 16) \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$ . Quoted errors were derived using conventional error propagation analysis and reflect uncertainties associated with both the F atom yield and the measurement of the slope in Figure 2. To map out the spectrum, experiments were performed to measure the initial absorbance between 225 and 275 nm following the radiolysis pulse. The initial absorbances were scaled to that at 250 nm. The results are plotted in Figure 3 and given in Table 1.

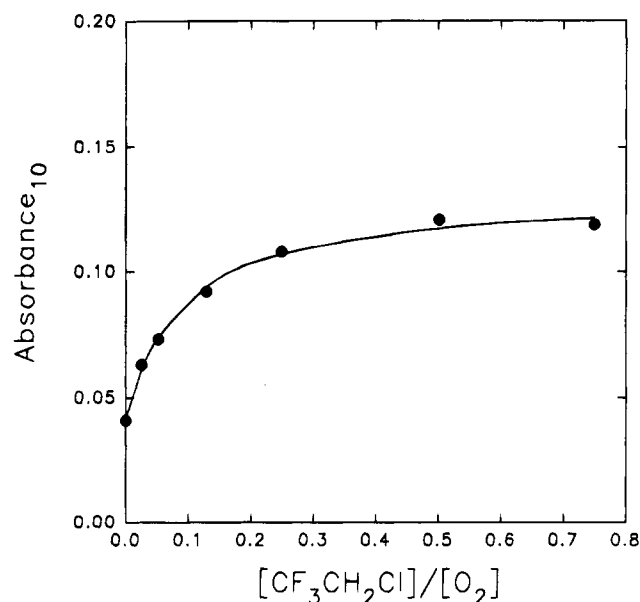

**The  $\text{F} + \text{CF}_3\text{CH}_2\text{Cl}$  Reaction.** To determine the rate constant for the  $\text{F} + \text{CF}_3\text{CH}_2\text{Cl}$  reaction,  $\text{O}_2$  was added to the system. After the radiolysis pulse, reactions 8 and 11 compete for the variable F atoms.

$\text{CF}_3\text{CClH}$  radicals formed in reaction 8 will add  $\text{O}_2$  to give the corresponding peroxy radicals.

A series of experiments was performed using a monitoring wavelength of 250 nm, reaction mixtures of 40 mbar of  $\text{O}_2$ , 950 mbar of  $\text{SF}_6$ , and 0–20.2 mbar of  $\text{CF}_3\text{CH}_2\text{Cl}$ , with the radiolysis dose fixed at 50% of full dose. Figure 4 shows the maximum transient absorbance as a function of the  $[\text{CF}_3\text{CH}_2\text{Cl}]/[\text{O}_2]$

**Figure 4.** Maximum transient absorbance as a function of the  $[\text{CF}_3\text{CH}_2\text{Cl}]/[\text{O}_2]$  ratio at 250 nm.

$\text{Cl}]/[\text{O}_2]$  ratio. As seen from the figure, the absorption was small at low  $[\text{CF}_3\text{CH}_2\text{Cl}]/[\text{O}_2]$  ratios and increased as the  $[\text{CF}_3\text{CH}_2\text{Cl}]/[\text{O}_2]$  ratio was increased to 0.5. Further increase in the  $[\text{CF}_3\text{CH}_2\text{Cl}]/[\text{O}_2]$  ratio had no significant effect on the transient absorption maximum. At low  $\text{CF}_3\text{CH}_2\text{Cl}$  concentrations,  $\text{FO}_2$  radicals are mainly formed and, on a per molecule basis,  $\text{FO}_2$  radicals absorb less than  $\text{CF}_3\text{CClHO}_2$  radicals. As the  $\text{CF}_3\text{CH}_2\text{Cl}$  concentration is increased  $\text{CF}_3\text{CClHO}_2$  radicals are formed at the expense of  $\text{FO}_2$  radicals and the transient absorption maximum increases. The following expression was fit to the data:

$$A_{\text{max}} = \{A_{\text{FO}_2} + A_{\text{CF}_3\text{CClHO}_2}(k_8/k_{11})[\text{CF}_3\text{CH}_2\text{Cl}]/[\text{O}_2]\} / \{1 + (k_8/k_{11})[\text{CF}_3\text{CH}_2\text{Cl}]/[\text{O}_2]\}$$

where  $A_{\text{max}}$  is the maximum absorbance,  $A_{\text{FO}_2}$  is the maximum absorbance expected if only  $\text{FO}_2$  radicals are produced, and  $A_{\text{CF}_3\text{CClHO}_2}$  is the maximum absorbance expected if  $\text{CF}_3\text{CClHO}_2$  were the sole absorbing species. Parameters  $A_{\text{FO}_2}$ ,  $A_{\text{CF}_3\text{CClHO}_2}$ , and  $k_8/k_{11}$  were varied simultaneously. The best fit was obtained with  $k_8/k_{11} = (10.8 \pm 3.3)$ . Quoted errors are 2 standard deviations. Using  $k_{11} = 1.9 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ ,<sup>5</sup> we derive  $k_8 = (2.0 \pm 0.6) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ .

It is surprising that in Figure 4 the ratio of the asymptote to the y-axis intercept,  $A_{\text{CF}_3\text{CClHO}_2}/A_{\text{FO}_2}$ , is 2.75 compared to the expected value of 2.0 ( $2.58 \times 10^{-18}$  [this work]/ $1.30 \times 10^{-18}$  [ref 5]). The uncertainties in absorption cross sections for  $\text{CF}_3\text{CClHO}_2$  and  $\text{FO}_2$  are both approximately 10%. Thus, we would expect the ratio to be within 10–20% of 2.0. The fact that it is not is probably due to uncertainties in measurement of the rather small absorbance in the absence of added  $\text{CF}_3\text{CClH}_2$ .

**UV Absorption Spectrum of  $\text{CF}_3\text{CClHO}_2$  Radicals.** A series of experiments was performed to determine the optimal experimental conditions for converting F atoms into  $\text{CF}_3\text{CClHO}_2$  radicals. Possible interfering secondary chemistry when radiolysing  $\text{CF}_3\text{CH}_2\text{Cl}/\text{O}_2/\text{SF}_6$  mixtures include

Figure 2 shows the maximum absorption vs the radiolysis dose for mixtures of 40 mbar of  $\text{CF}_3\text{CClH}_2$ , 20 mbar of  $\text{O}_2$ , and 940

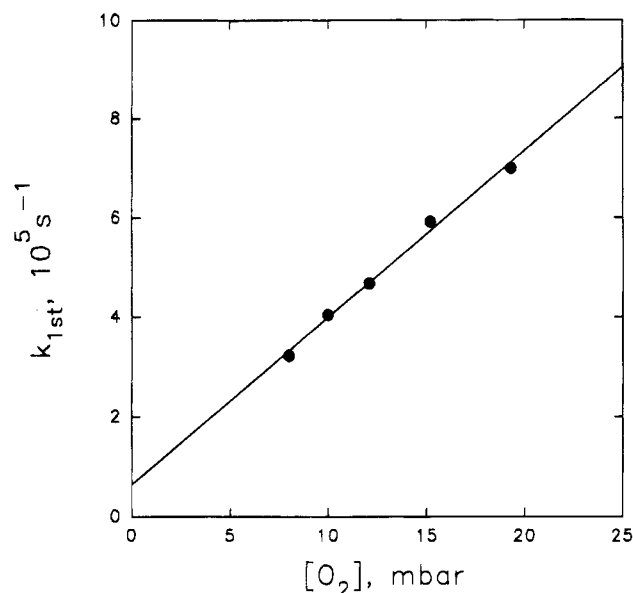

mbar of SF<sub>6</sub> at 250 nm. As seen from Figure 2, the maximum transient absorption increased linearly with the dose up to 50% of full dose. At full dose the maximum transient absorbance falls below that expected from a linear extrapolation of the low dose results. We ascribe this behavior to unwanted radical-radical reactions such as (12)–(14) at high initial radical concentration. A linear least-squares fit through the low dose data gives a slope of  $0.23 \pm 0.01$ .

The maximum transient absorbance following radiolysis of mixtures of 40 mbar of CF<sub>3</sub>CH<sub>2</sub>Cl, 20 mbar of O<sub>2</sub>, and 940 mbar of SF<sub>6</sub> was studied at short times (40 μs). The radiolysis dose used was 50% of full dose and the absorption wavelength was varied between 225 and 290 nm. Due to the competition for F atoms via reactions 8 and 11 some of the F atoms will react with O<sub>2</sub> instead of CF<sub>3</sub>CH<sub>2</sub>Cl. With the pressures used and the rate constants  $k_8 = (2.0 \pm 0.6) \times 10^{-12}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup> and  $k_{11} = 1.9 \times 10^{-13}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup> we can calculate that 4.5% of the F atoms react with O<sub>2</sub>. We therefore have to correct the measured absorbances for absorption by FO<sub>2</sub> radicals. Using the following information (i) the F atom yield of  $(2.8 \pm 0.3) \times 10^{15}$  4 at full dose and 1000 mbar of SF<sub>6</sub>, (ii)  $\sigma_{FO_2}$  (250 nm) =  $130 \times 10^{-20}$  cm<sup>2</sup> molecule<sup>-1</sup>,<sup>5</sup> and (iii) the slope of the straight line through the low dose data ( $0.23 \pm 0.01$ ), we calculate the absorption cross section for CF<sub>3</sub>CCIHO<sub>2</sub> at 250 nm to be  $(258 \pm 30) \times 10^{-20}$  cm<sup>2</sup> molecule<sup>-1</sup>. The quoted errors reflect uncertainties in the slope of the data in Figure 2 and in the calculation of the F atom yield. To map out the spectrum, experiments were performed to measure the initial absorbance between 225 nm and 290 nm. The maximum initial absorbances were scaled to that at 250 nm and corrected for FO<sub>2</sub> to obtain absolute absorption cross sections. The absorption cross sections are plotted in Figure 3 and listed in Table 1.

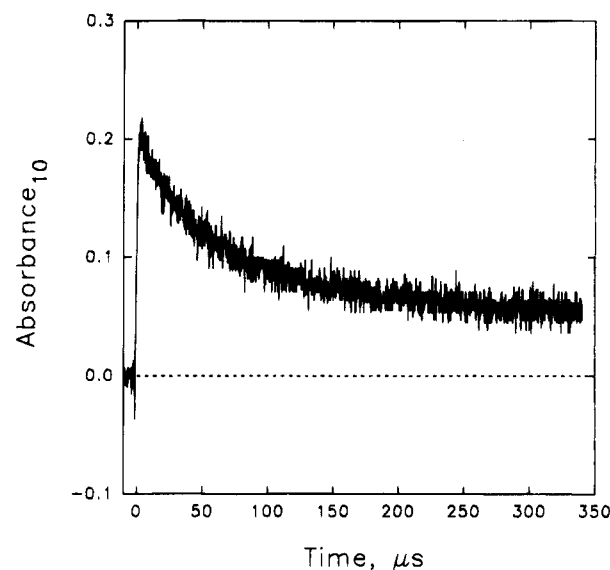

**The CF<sub>3</sub>CCIHO<sub>2</sub> + O<sub>2</sub> Reaction.** The reaction of CF<sub>3</sub>CCIHO<sub>2</sub> radicals with O<sub>2</sub> was studied by observing the formation of CF<sub>3</sub>-CCIHO<sub>2</sub> radicals following the radiolysis of CF<sub>3</sub>CCIHO<sub>2</sub>/O<sub>2</sub>/SF<sub>6</sub> mixtures at short times (20 μs). The conditions were 50 mbar of CF<sub>3</sub>CCIHO<sub>2</sub>, 5.2–19.3 mbar of O<sub>2</sub>, and SF<sub>6</sub> added up to 1 bar total pressure. The absorption transients were well fitted using first-order kinetics, pseudo-first-order rate constants are plotted as a function of the O<sub>2</sub> concentration in Figure 5. Linear least-squares analysis of the data in Figure 5 gives  $k_2 = (1.4 \pm 0.1) \times 10^{-12}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup>.

**The CF<sub>3</sub>CCIHO<sub>2</sub> Self-Reaction.** Experiments were performed using 40 mbar of CF<sub>3</sub>CH<sub>2</sub>Cl, 20 mbar of O<sub>2</sub>, and 940 mbar of SF<sub>6</sub> at a monitoring wavelength of 250 nm. The UV light path length was 80 cm and the radiolysis dose was varied. Figure 6 shows a typical transient absorption, following the pulse radiolysis of CF<sub>3</sub>CCIHO<sub>2</sub>/O<sub>2</sub>/SF<sub>6</sub> mixtures. This decay can be fitted with a nonlinear least-squares second-order fit. We ascribe the decay to the CF<sub>3</sub>CCIHO<sub>2</sub> self-reaction. Figure 7 shows a plot of the reciprocal half-life obtained from the fit as a function of the initial maximum absorption. The straight line through the data is a linear least fit with a slope of  $(9.82 \pm 0.37) \times 10^4$  s<sup>-1</sup>. This slope is related to the rate constant for the self-reaction  $k_{6obs}$ , by the expression  $\text{slope} = (k_{6obs} \times 2 \ln(10))/(\sigma(\text{CF}_3\text{-CCIHO}_2) \times 80)$ . Hence, we derive  $k_{6obs} = (4.4 \pm 0.5) \times 10^{-12}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup>. Quoted errors reflect uncertainties in both  $\sigma(\text{CF}_3\text{CCIHO}_2)$  and the slope in Figure 7.

**The CF<sub>3</sub>CCIHO<sub>2</sub> + NO Reaction.** To study the kinetics of reaction 3, experiments were performed where the transient absorption at 400 nm was monitored following radiolysis of NO/CF<sub>3</sub>CH<sub>2</sub>Cl/O<sub>2</sub>/SF<sub>6</sub> mixtures. An example of an absorption trace is shown in Figure 8. The observed absorption is ascribed to the formation of NO<sub>2</sub> via reaction 3. To extract a value for  $k_3$  from traces such as that shown in Figure 8 the trace was fitted by using the expression  $A(t) = (A_\infty - A_0) \times [1 - \exp(-k_3^{\text{st}}t)] + A_0$ , where  $A(t)$  is the absorbance as a function of time,  $A_\infty$  is the absorbance at infinite time,  $k_3^{\text{st}}$  is the pseudo-first-order appearance rate of NO<sub>2</sub>, and  $A_0$  is the extrapolated absorbance at  $t = 0$ . The fit was started 3 μs after the radiolysis pulse to allow for the formation of the peroxy radical. A plot of the measured pseudo-first-order rate constant vs the NO concentration is shown in Figure 9. As seen from Figure 9, the pseudo-first-order rate constant,  $k_3^{\text{st}}$ , increased linearly with [NO]. Linear least-squares analysis of the data in Figure 9 gives  $k_3 = (1.0 \pm 0.3) \times 10^{-11}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup>, with an insignificant intercept of  $(-0.26 \pm 3.95) \times 10^4$  s<sup>-1</sup>.

**Figure 5.** Plot of the pseudo-first-order rate of CF<sub>3</sub>CCIHO<sub>2</sub> formation vs [O<sub>2</sub>].

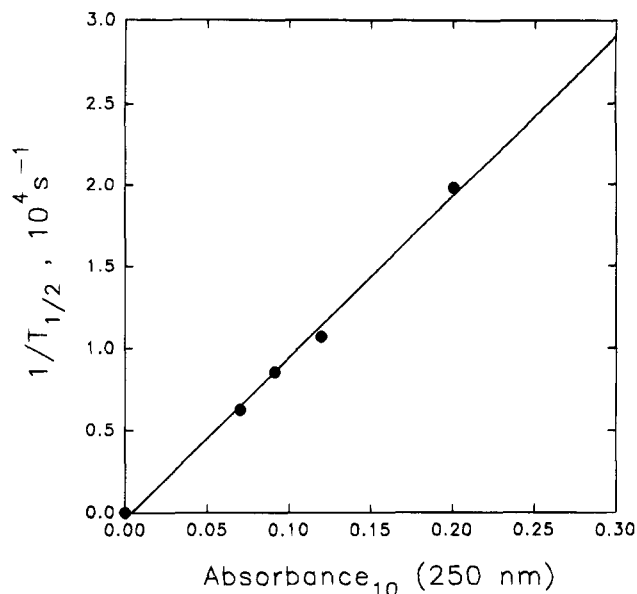

**Figure 6.** Absorption transient at 250 nm following the pulse radiolysis of a mixture of 40 mbar of CF<sub>3</sub>CH<sub>2</sub>Cl, 20 mbar of O<sub>2</sub>, and 940 mbar of SF<sub>6</sub>.

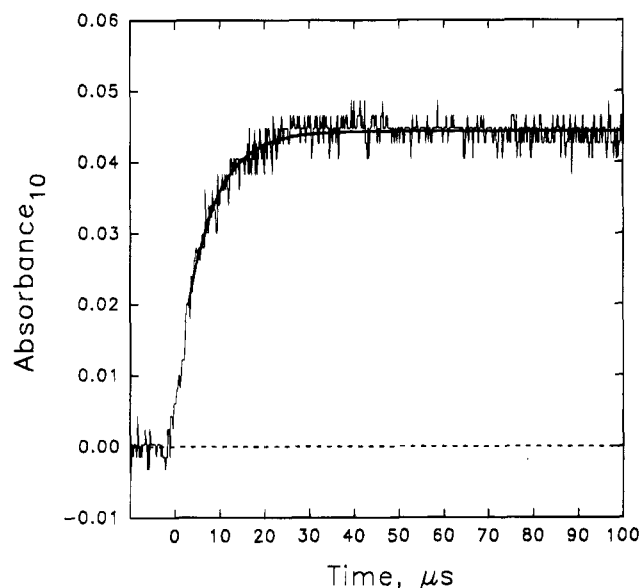

The increase in absorbance at 400 nm can be combined with the literature value of  $\sigma(\text{NO}_2)(400\text{nm}) = 6.0 \times 10^{-19}$  cm<sup>2</sup> molecule<sup>-1</sup> (average of values over wavelength range given in ref 6) to calculate the yield of NO<sub>2</sub> in this system. The yield of NO<sub>2</sub> in the experiments given in Figure 9, expressed as moles of NO<sub>2</sub> produced per mole of F atoms consumed, was  $97 \pm 9\%$ .

**The CF<sub>3</sub>CCIHO<sub>2</sub> + NO<sub>2</sub> Reaction.** Following the radiolysis of CF<sub>3</sub>CCIHO<sub>2</sub>/NO<sub>2</sub>/O<sub>2</sub>/SF<sub>6</sub> mixtures a decrease in the absorption was observed at 400 nm. This is ascribed to the loss of NO<sub>2</sub>

Following the radiolysis of CF<sub>3</sub>CCIHO<sub>2</sub>/NO<sub>2</sub>/O<sub>2</sub>/SF<sub>6</sub> mixtures a decrease in the absorption was observed at 400 nm. This is ascribed to the loss of NO<sub>2</sub>

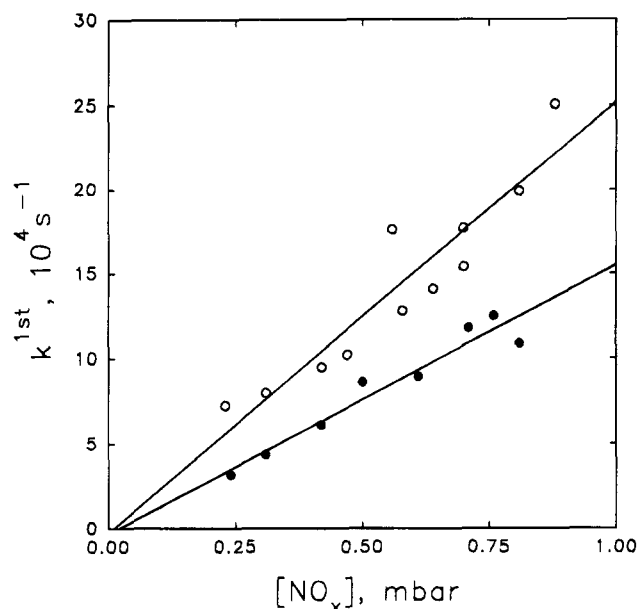

**Figure 7.** Reciprocal half-lives vs maximum absorbance at 250 nm for mixtures of 40 mbar of  $\text{CF}_3\text{CH}_2\text{Cl}$ , 20 mbar of  $\text{O}_2$ , and 940 mbar of  $\text{SF}_6$ .

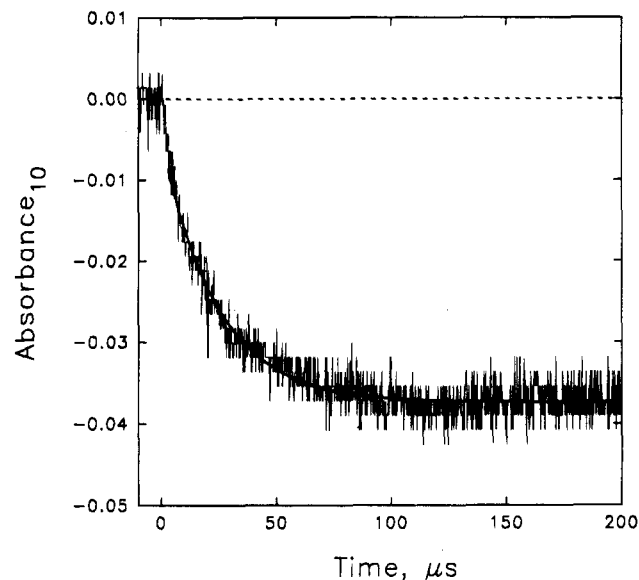

**Figure 8.** Transient absorbance at 400 nm observed following pulse radiolysis (dose = 50% of maximum) of a mixture of 0.64 mbar of  $\text{NO}$ , 40 mbar of  $\text{CF}_3\text{CClH}_2$ , 20 mbar of  $\text{O}_2$ , and 940 mbar of  $\text{SF}_6$ . The solid line is a first-order fit to the experimental data.

via reaction 4. An example of a typical experimental transient absorption is shown in Figure 10. The smooth solid line in Figure 10 is a first-order fit using the expression  $\text{Abs}(t) = (A_{\text{inf}} - C) \times [1 - \exp(-k^{\text{1st}}t)] + C$ , where  $\text{Abs}(t)$  is the absorbance as a function of time,  $A_{\text{inf}}$  is the absorbance at infinite time,  $k^{\text{1st}}$  is the pseudo-first-order loss rate of  $\text{NO}_2$ , and  $C$  is the extrapolated absorbance at  $t = 0$ . The decay was observed to follow first-order-kinetics in all cases. Of all the species initially present in the reaction cell only  $\text{NO}_2$  absorbs significantly at 400 nm. Control experiments were performed in which  $\text{SF}_6/\text{CF}_3\text{CH}_2\text{Cl}$ ,  $\text{SF}_6/\text{CF}_3\text{CH}_2\text{Cl}/\text{O}_2$ ,  $\text{SF}_6/\text{O}_2$ , or just  $\text{SF}_6$  were radiolyzed; no change in absorption at 400 nm was observed. A plot of the measured pseudo-first-order decay rate vs the  $\text{NO}_2$  concentration is shown in Figure 9. Linear least-squares analysis of the data in Figure 9 gives  $k_4 = (6.4 \pm 1.5) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ , with an insignificant intercept of  $(0.32 \pm 1.96) \times 10^{-4} \text{ s}^{-1}$ . The decrease in absorption at 400 nm can be combined with value of  $\sigma_{\text{NO}_2}(400 \text{ nm}) = 6.0 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$  to calculate the loss of  $\text{NO}_2$  in this system. The

**Figure 9.** Plot of  $k^{\text{1st}} [\text{NO}]$  (open symbols) and vs  $[\text{NO}_2]$  (closed symbols).

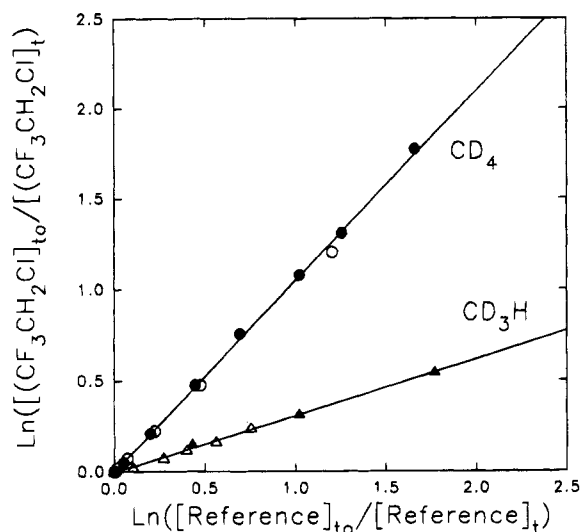

**Figure 10.** Transient absorbance at 400 nm observed following pulse radiolysis (dose = 50% of maximum) of a mixture of 0.31 mbar of  $\text{NO}_2$ , 40 mbar of  $\text{CF}_3\text{CClH}_2$ , 20 mbar of  $\text{O}_2$ , and 940 mbar of  $\text{SF}_6$ . The solid line is a first-order fit to the experimental data.

loss of  $\text{NO}_2$  in the experiments given in Figure 10, expressed as moles of  $\text{NO}_2$  consumed per mole of F atoms consumed, was  $93 \pm 12\%$ .

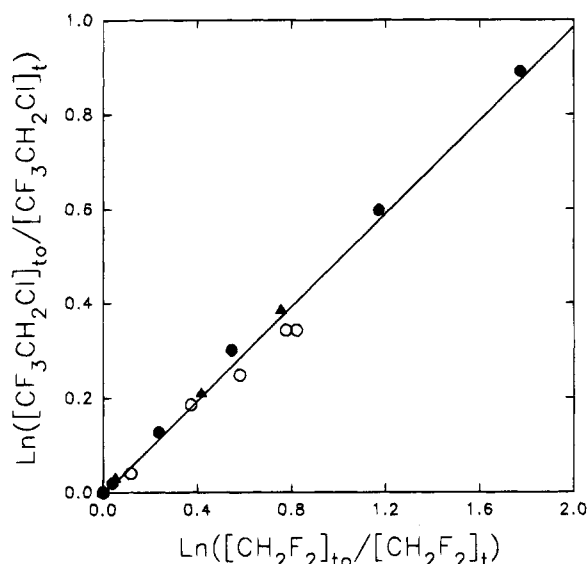

**3.2. Results from FTIR-Smog Chamber System.** *Relative Rate Studies of the Reactions of Cl and F Atoms with  $\text{CF}_3\text{-CH}_2\text{Cl}$ .* Prior to investigating the atmospheric fate of  $\text{CF}_3\text{-CClHO}$  radicals, a series of relative rate experiments was performed using the FTIR system to investigate the kinetics of the reactions 15 and 8. The techniques used are described in detail elsewhere.<sup>7</sup> Photolysis of molecular halogen was used as a source of halogen atoms.

The kinetics of reaction 15 were measured relative to (16) and

**Figure 11.** Plot of the decay of  $\text{CF}_3\text{CH}_2\text{Cl}$  vs those of  $\text{CD}_4$  and  $\text{CHD}_3$  in 700 Torr of air (filled symbols) or nitrogen (open symbols) at 296 K in the presence of Cl atoms.

**Figure 12.** Plot of the decay of  $\text{CF}_3\text{CH}_2\text{Cl}$  vs that of  $\text{CH}_2\text{F}_2$  in 700 Torr of air (filled symbols) or nitrogen (open symbols) at 296 K in the presence of F atoms.

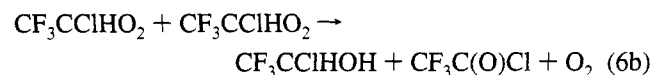

(17), reaction 8 was measured relative to (19).

The observed losses of  $\text{CF}_3\text{CH}_2\text{Cl}$  by  $\text{CD}_3\text{H}$  and  $\text{CD}_4$  in the presence of Cl atoms, and  $\text{CF}_3\text{CH}_2\text{Cl}$  vs  $\text{CH}_2\text{F}_2$  in the presence of F atoms, are shown in Figures 11 and 12, respectively. There was no discernible difference between data obtained in 700 Torr of  $\text{N}_2$  or air. In the study of the reaction of F atoms with  $\text{CF}_3\text{CH}_2\text{Cl}$  care must be taken to avoid, or correct for, complications caused by the possible generation of Cl atoms following reaction 8. As a check for such complications, the initial concentration ratio  $[\text{CF}_3\text{CH}_2\text{Cl}]/[\text{CH}_2\text{F}_2]$  was varied over the range 0.8–3.6 with no observable effect on the measured value of  $k_8/k_{19}$ . It seems reasonable to conclude that our measurement of  $k_8/k_{19}$  is free from any complications involving the formation of Cl atoms. Linear least-squares analyses of the data in Figures 11 and 12 give  $k_{15}/k_{16} = 0.31 \pm 0.02$ ,  $k_{15}/k_{17} = 1.05 \pm 0.05$ , and  $k_8/k_{19} = 0.49 \pm 0.04$ . Using  $k_{16} = 2.3 \times 10^{-14}$ ,<sup>7</sup>  $k_{17} = 6.1 \times$

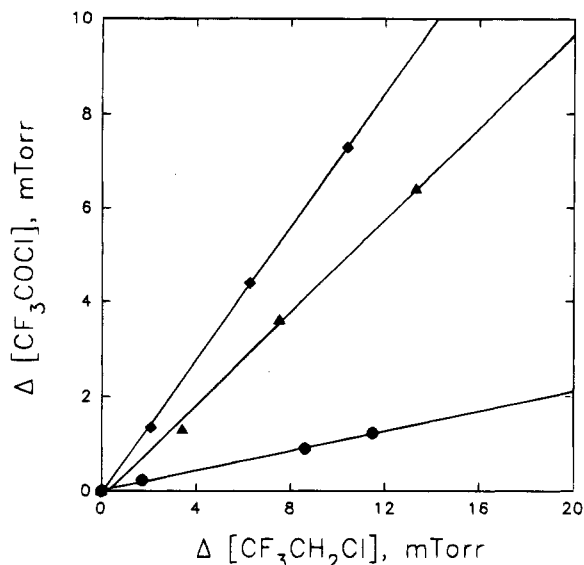

$10^{-15}$ ,<sup>7</sup> and  $k_{19} = 4.3 \times 10^{-12}$  s<sup>-1</sup> gives  $k_{15} = (7.1 \pm 0.5) \times 10^{-15}$ ,  $k_{15} = (6.4 \pm 0.3) \times 10^{-15}$ , and  $k_8 = (2.1 \pm 0.2) \times 10^{-12}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup>, respectively. We estimate that potential systematic errors associated with uncertainties in the reference rate constants could add additional 10 and 20% to the uncertainty ranges for  $k_{15}$  and  $k_8$ , respectively. Propagating this additional uncertainty gives values of  $k_{15} = (7.1 \pm 0.9) \times 10^{-15}$ ,  $k_{15} = (6.4 \pm 0.7) \times 10^{-15}$ , and  $k_8 = (2.1 \pm 0.5) \times 10^{-12}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup>. We choose to cite a final value of  $k_{15}$  which is an average of those determined using the two different reference compounds together with error limits which encompass the extremes of the two individual determinations. Hence,  $k_{15} = (6.8 \pm 1.2) \times 10^{-15}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup>. The quoted error reflects the accuracy of the measurements. The value of  $k_8$  determined using the FTIR technique is in good agreement with the determination of  $k_8 = (2.0 \pm 0.6) \times 10^{-12}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup> using the pulse radiolysis technique in the present work. There are no literature data for  $k_8$  with which to compare our results. The value of  $k_{15}$  reported herein is consistent with the experimental uncertainties with the previous absolute measurement of  $k_{15} = 5.9 \times 10^{-15}$  cm<sup>3</sup> molecule<sup>-1</sup> s<sup>-1</sup> by Jourdain et al.<sup>9</sup> The consistency in the values of  $k_8$  measured using the pulse radiolysis and FTIR relative rate techniques suggests the absence of any significant reactive impurities in the sample of  $\text{CF}_3\text{CH}_2\text{Cl}$  used in this work.

**Study of the Atmospheric Fate of  $\text{CF}_3\text{CClHO}$  Radicals.** To determine the atmospheric fate of the alkoxy radical  $\text{CF}_3\text{CClHO}$  experiments were performed in which  $\text{CF}_3\text{CH}_2\text{Cl}/\text{O}_2/\text{Cl}_2$  and  $\text{CF}_3\text{CH}_2\text{Cl}/\text{O}_2/\text{F}_2$  mixtures at a total pressure of 700 Torr made up with  $\text{N}_2$  diluent were irradiated in the FTIR–smog chamber system. The loss of  $\text{CF}_3\text{CH}_2\text{Cl}$  and the formation of products were monitored by FTIR spectroscopy.  $\text{CF}_3\text{CClHO}$  radicals formed in the chamber in reaction 6a will either react with  $\text{O}_2$  to give the aldehyde  $\text{CF}_3\text{C(O)Cl}$  (reaction 20), dissociate to give  $\text{HC(O)Cl}$  and  $\text{CF}_3$  radicals (reaction 21), eliminate a Cl atom to give  $\text{CF}_3\text{CHO}$  (reaction 22), or undergo intramolecular HCl elimination to give  $\text{CF}_3\text{CO}$  radicals (reaction 23).

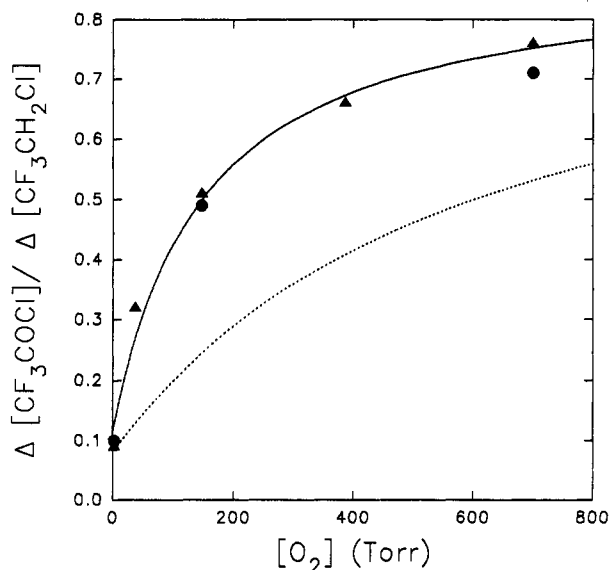

$\text{CF}_3$  radicals formed in reaction 21 are expected to be converted into  $\text{CF}_3\text{OH}$  via addition of  $\text{O}_2$ , reaction with peroxy radicals ( $\text{CF}_3\text{CClHO}_2$  or  $\text{CF}_3\text{O}_2$ ) to give  $\text{CF}_3\text{O}$  radicals, which will then abstract a H atom from  $\text{CF}_3\text{CH}_2\text{Cl}$ .

The observed products formed during the oxidation of  $\text{CF}_3\text{CH}_2\text{Cl}$  were  $\text{CF}_3\text{C(O)Cl}$ , CO,  $\text{CO}_2$ ,  $\text{CF}_3\text{OH}$ , and HCl. Let us consider  $\text{CF}_3\text{C(O)Cl}$ . Figure 13 shows the results obtained from the UV irradiation of three different  $\text{CF}_3\text{CH}_2\text{Cl}/\text{Cl}_2/\text{N}_2/\text{O}_2$  mixtures. As seen in Figure 13, the observed formation of  $\text{CF}_3\text{C(O)Cl}$  was a linear function of the  $\text{CF}_3\text{CH}_2\text{Cl}$  loss. Such linearity suggests, but does not prove, that secondary loss of  $\text{CF}_3\text{C(O)Cl}$  is not a complication in this work. To provide information on the behavior of  $\text{CF}_3\text{C(O)Cl}$  in the chamber, mixtures of  $\text{CF}_3\text{C(O)Cl}$  in air, with and without added  $\text{Cl}_2$ , were prepared, allowed to stand in the dark for 5 min and then

**Figure 13.** Formation of  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  as a function of the loss of  $\text{CF}_3\text{CH}_2\text{Cl}$  following the irradiation of mixtures of 98–100 mTorr of  $\text{CF}_3\text{CH}_2\text{Cl}$ , 0.4–0.5 Torr of  $\text{Cl}_2$ , and 2.38 Torr (circles), 147 Torr (triangles), or 700 Torr of  $\text{O}_2$  (diamonds) in 700 Torr total pressure made up where appropriate with  $\text{N}_2$  diluent.

**Figure 14.** Observed yield of  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  following F atom (triangles) or Cl atom (circles) initiated oxidation of  $\text{CF}_3\text{CH}_2\text{Cl}$  in 700 Torr total pressure of  $\text{N}_2/\text{O}_2$  as a function of the  $\text{O}_2$  partial pressure. The solid line is a fit to the data, see text for details. The dotted line represents the observed yield of  $\text{CF}_3\text{C}(\text{O})\text{F}$  following Cl atom initiated oxidation of  $\text{CF}_3\text{CH}_2\text{F}$  taken from ref 12.

irradiated for 5 min. No loss ( $<1\%$ ) of  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  was discernible suggesting that under the present experimental conditions,  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  is not lost by heterogeneous processes, photolysis, or reaction with Cl atoms. Linear least-squares analysis of the data in Figure 13 provides molar yields of  $\text{CF}_3\text{C}(\text{O})\text{Cl}$ . A series of experiments was performed using a range of  $\text{O}_2$  partial pressures all at 700 Torr total pressure with  $\text{N}_2$  diluent. Both Cl and F atom initiation were employed. As seen from Figure 14, the molar yield of  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  was found to increase with increasing  $\text{O}_2$  partial pressure. Experiments employing Cl and F atom initiation gave indistinguishable results. There are two known sources of  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  in the present experiments: reactions 6b and 20. The fact that the  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  yield is  $\text{O}_2$  dependent shows that loss mechanisms other than reaction 20 compete for the available  $\text{CF}_3\text{CClHO}$  radicals. A reasonable question at this point is "What other loss mechanism(s) competes for  $\text{CF}_3\text{CClHO}$  radicals?" As

discussed above, three possibilities exist: reactions 21, 22, or 23. Unfortunately, on the basis of the present experiments we are unable to determine the relative importance of these reactions. The problem lies in unavoidable secondary reactions of  $\text{HC}(\text{O})\text{Cl}$  and  $\text{CF}_3\text{C}(\text{O})\text{H}$  which serve as markers for reactions 21 and 22, respectively. IR features attributable to  $\text{HC}(\text{O})\text{Cl}$  ( $<0.2$  mTorr) and  $\text{CF}_3\text{C}(\text{O})\text{H}$  ( $<1.5$  mTorr) were searched for but not found. However, the absence of significant quantities of these carbonyl products does not prove that reactions 21 and 22 are unimportant.  $\text{HC}(\text{O})\text{Cl}$  and  $\text{CF}_3\text{CHO}$  (if formed) are likely to be consumed by secondary reactions involving Cl atoms (in all experiments), F atoms (in those experiments employing F atom initiation), or  $\text{CF}_3\text{O}$  radicals (in all experiments). Kinetic data are available concerning the reactivity of  $\text{CF}_3\text{CHO}$  towards F and Cl atoms,<sup>10</sup>  $\text{HC}(\text{O})\text{Cl}$  toward Cl atoms,<sup>11</sup> and  $\text{CF}_3\text{CH}_2\text{Cl}$  toward F and Cl atoms (this work). Hence, estimates of the importance of such secondary reactions can be provided. Compared to  $\text{CF}_3\text{CH}_2\text{Cl}$ ,  $\text{CF}_3\text{CHO}$  is more reactive toward F and Cl atom attack by factors of 265 and 13, respectively, and  $\text{HC}(\text{O})\text{Cl}$  is more reactive toward Cl atoms by a factor of 115. The reactivity of F atoms toward  $\text{HC}(\text{O})\text{Cl}$  is unknown but might reasonably be expected to be substantially greater than that toward  $\text{CF}_3\text{CH}_2\text{Cl}$ . Similarly, the reactivity of  $\text{CF}_3\text{O}$  radicals toward  $\text{CF}_3\text{CHO}$  and  $\text{HC}(\text{O})\text{Cl}$  has not been reported but is likely to be greater than that toward  $\text{CF}_3\text{CH}_2\text{Cl}$ . Potential complications associated with secondary chemistry can be reduced by increasing the initial concentrations and using low conversions ( $<1\%$ ) of  $\text{CF}_3\text{CH}_2\text{Cl}$ . This course of action was not pursued because the stated purity of the  $\text{CF}_3\text{CH}_2\text{Cl}$  used was  $>99\%$ , hence if conversions of  $<1\%$  were employed it would be impossible to guarantee that the observed products were not merely attributable to chemistry involving impurities in the  $\text{CF}_3\text{CH}_2\text{Cl}$  sample. Secondary chemistry is unavoidable in the present experiments and precludes the identification of loss mechanisms for  $\text{CF}_3\text{CClHO}$  radicals other than reaction 20.

The dependence of  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  yield on  $\text{O}_2$  partial pressure shown in Figure 14 is reminiscent of that of  $\text{CF}_3\text{C}(\text{O})\text{F}$  from  $\text{CF}_3\text{CFHO}$  radicals.<sup>12</sup> The dotted line in Figure 14 is the  $\text{CF}_3\text{C}(\text{O})\text{F}$  yield observed following irradiation of  $\text{CF}_3\text{CH}_2\text{F}/\text{Cl}_2/\text{N}_2/\text{O}_2$  mixtures at 700 Torr total pressure.<sup>12</sup> As discussed previously,<sup>12</sup> the simplest chemical mechanism that explains the observed dependence of the  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  product yield on the  $\text{O}_2$  partial pressure consists of (6a), (6b), (20), and (21) (we ignore for the moment reactions 22 and 23). Using this chemical mechanism, it can be shown that the dependence of the molar yield of  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  should follow the expression

$$\text{CF}_3\text{C}(\text{O})\text{Cl yield} = Y_0 + (1 - 2Y_0) \left\{ \frac{(k_{20}/k_{21})[\text{O}_2]}{1 + (k_{20}/k_{21})[\text{O}_2]} \right\} \quad (\text{I})$$

where  $Y_0$  is the  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  yield extrapolated to zero oxygen pressure,  $k_{20}$  is the bimolecular rate constant for reaction 20,  $k_{21}$  is the unimolecular rate constant for reaction 21, and  $[\text{O}_2]$  is the partial pressure of oxygen. The solid line in Figure 14 is a fit of expression I to the observed  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  yield. As seen from Figure 14, the dependence of the  $\text{CF}_3\text{C}(\text{O})\text{Cl}$  yields on  $[\text{O}_2]$  is well described by expression I. The least-squares fit to the data in Figure 14 gives  $Y_0 = 0.11 \pm 0.04$ , and  $k_{20}/k_{21} = (2.1 \pm 0.4) \times 10^{-19} \text{ cm}^3 \text{ molecule}^{-1}$ . The analogous data for  $\text{CF}_3\text{CFHO}$  radicals (given by the dotted line in Figure 14) gave  $Y_0$  (for  $\text{CF}_3\text{CFHO}_2$  radicals)  $= 0.08 \pm 0.03$  and  $k(\text{CF}_3\text{CFHO} + \text{O}_2 \rightarrow \text{CF}_3\text{C}(\text{O})\text{F} + \text{HO}_2)/k(\text{CF}_3\text{CFHO} \rightarrow \text{CF}_3 + \text{HC}(\text{O})\text{F}) = (5.1 \pm 0.7) \times 10^{-20} \text{ cm}^3 \text{ molecule}^{-1}$ . The values of  $Y_0$ , which provide measures of the importance of the molecular channel (i.e., (6b)) in the self-reactions of  $\text{CF}_3\text{CClHO}_2$  and  $\text{CF}_3\text{CFHO}_2$  radicals, are indistinguishable. For a given  $\text{O}_2$  partial pressure,

CF<sub>3</sub>CClHO radicals are approximately 4 times more prone to reaction with O<sub>2</sub> than are CF<sub>3</sub>CFHO radicals.

The atmospheric chemistry of CF<sub>3</sub>CFHO radicals has been studied extensively and it has been established that reaction with O<sub>2</sub> (giving CF<sub>3</sub>C(O)F and HO<sub>2</sub> radicals) competes with C–C bond scission (giving CF<sub>3</sub> radicals and HC(O)F).<sup>12–14</sup> In light of the similar dependencies of CF<sub>3</sub>C(O)X (X = Cl or F) yields on the O<sub>2</sub> partial pressure, we believe (but can not prove) that C–C bond scission (i.e., reaction 21) is the loss process that competes for CF<sub>3</sub>CClHO radicals in the present experiments. In the rest of this paper we proceed on the assumption that reactions 22 and 23 are of negligible importance.

The data in Figure 14 shows that the competition between reaction with O<sub>2</sub> and decomposition is tilted more toward reaction with O<sub>2</sub> for CF<sub>3</sub>CClHO radicals than for CF<sub>3</sub>CFHO radicals. This observation implies either a strengthening of the C–C bond in CF<sub>3</sub>CClHO radicals compared to CF<sub>3</sub>CFHO, or a weakening of the C–H bond, or both. Barry et al.<sup>15</sup> have noted that in the series of alkoxy radicals of the general formula CX<sub>3</sub>CFHO (where X = H or F) the importance of reaction with O<sub>2</sub> compared to C–C bond scission increases with the polarity of the C–C bond. This behavior was ascribed to an increase in C–C bond strength with increasing polarity. Since CF<sub>3</sub>CClHO radicals are more polar than CF<sub>3</sub>CFHO radicals the increased importance of reaction with O<sub>2</sub> in the atmospheric chemistry of CF<sub>3</sub>CClHO radicals supports the hypothesis by Barry et al.<sup>15</sup> Finally, before we leave this section it is relevant note that as seen in Figure 14 the same product yields were observed using either F or Cl atom initiation. This suggests that CF<sub>3</sub>CHCl radicals are formed as the major, if not sole, product of reaction of F atoms with CF<sub>3</sub>CH<sub>2</sub>Cl.

#### 4. Discussion

Following release into the atmosphere, CF<sub>3</sub>CH<sub>2</sub>Cl will react predominantly with hydroxyl radicals. The atmospheric lifetime of CF<sub>3</sub>CH<sub>2</sub>Cl with respect to reaction with OH is 4–5 years.<sup>16</sup> Reaction with OH gives CF<sub>3</sub>CClH radicals which are rapidly (within 1 μs), converted into the corresponding peroxy radical, CF<sub>3</sub>CClHO<sub>2</sub>. Using  $k_3 = 1.0 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$  together with an estimated background tropospheric NO concentration of  $2.5 \times 10^8 \text{ cm}^{-3}$ ,<sup>17</sup> the lifetime of CF<sub>3</sub>CClHO<sub>2</sub> radicals with respect to reaction 3 is calculated to be 7 min. Reaction 3 is likely to be an important atmospheric loss of CF<sub>3</sub>CClHO<sub>2</sub> radicals. We have shown here that CF<sub>3</sub>CClHO<sub>2</sub> radicals react with NO to produce NO<sub>2</sub> and (by inference) CF<sub>3</sub>CClHO radicals.

Decomposition and reaction with O<sub>2</sub> are both important loss mechanisms for CF<sub>3</sub>CClHO radicals at 296 K and 700 Torr total pressure of N<sub>2</sub> diluent. Decomposition probably gives CF<sub>3</sub> radicals and HC(O)Cl. At 296 K, the rate constant ratio  $k_{20}/k_{21} = (2.1 \pm 0.4) \times 10^{-19} \text{ cm}^3 \text{ molecule}^{-1}$ . In 1 atm of air at 296 K, decomposition and reaction with O<sub>2</sub> are of approximately equal importance. In the earth's atmosphere the temperature is generally substantially lower than 296 K. The rates of reactions 20 and 21 will both decrease with decreasing temperature. Reaction 21 is a unimolecular decomposition and will be particularly sensitive to temperature. The average temperature of air between 0 and 10 km is 278 K.<sup>18</sup> If we assume that the difference in activation energies for reactions 20 and 21 is the same as that for the analogous reactions of CF<sub>3</sub>CFHO radicals (i.e., 7.2 kcal mol<sup>-1</sup>),<sup>12</sup> then the rate constant ratio  $k_{20}/k_{21}$  will be a factor of 2 lower at 278 K than at 296 K. We must consider the impact of decreasing total pressure and oxygen partial pressure with increasing altitude. The rate constant ratio  $k_{20}/k_{21} = (2.1 \pm 0.4) \times 10^{-19} \text{ cm}^3 \text{ molecule}^{-1}$  reported here is appropriate for 700 Torr total pressure.  $k_{21}$  is expected to be

sensitive to the total pressure while  $k_{20}$  is not, and the ratio  $k_{20}/k_{21}$  will increase as pressure is decreased. By analogy to the observed behavior of CF<sub>3</sub>CFHO radicals,<sup>12</sup> the effects of decreasing total pressure and decreasing O<sub>2</sub> concentration with increasing altitude will approximately cancel out. We conclude that reaction with O<sub>2</sub> is the dominant fate of CF<sub>3</sub>CClHO radicals, with decomposition via C–C bond scission making a minor, but nonnegligible, contribution. In the troposphere, CF<sub>3</sub>C(O)Cl will be incorporated into rain–cloud–sea water and undergo hydrolysis to CF<sub>3</sub>COOH which will then be rained out.<sup>19</sup> The atmospheric degradation products of HCFC-133a have lifetimes substantially less than that of the parent compound and are incapable of transporting significant amounts of chlorine to the stratosphere. CF<sub>3</sub>C(O)Cl produced in the upper stratosphere will photolyze to give CF<sub>3</sub> + CO + Cl.<sup>20–22</sup>
